ABSTRACT

Drug development relies on complexation to alter the pharmacological, toxicological, and physico-chemical characteristics of pharmaceuticals. Cefuroxime complexes of Copper (II) and Silver (I) were created in this work using a solvent-free method (mechanochemical). Physico-chemical techniques including infrared, UV/Visible, elemental analysis, melting temperature, solubility, and conductivity were used to describe the complexes. The complexes were hypothesized to have the formulas $[\text{Cu}(\text{CFU})_2\text{H}_2\text{O}]$ and $[\text{Ag}(\text{CFU})\text{NO}_3]$ based on the data, where CFU stands for cefuroxime. Utilizing the disc diffusion method, the antimicrobial efficacy of the synthesized complexes was evaluated against a variety of bacterial strains, including *Streptococcus pneumoniae*, *Bacillus subtilis*, *Salmonella typhi*, *Klebsiella pneumoniae*, *Escherichia coli*, Methicillin-resistant staphylococcus aureus (MRSA)

Article History: Received 10 July 2017, Accepted 25 August 2017, Available Online 27 September 2017

1. Introduction

The treatment of diseases remains an important and challenging problem because of a combination of factors including emerging infectious diseases and the increasing number of multi-drug resistance microbial pathogens. Despite the large number of antibiotics and chemotherapeutics available for medicinal use, at the same time the emergence of old and new antibiotic resistance witnessed in the last decades revealed a substantial discovery of new compounds endowed with antimicrobial activity, possibly acting through mechanism of action, which is distinct from those of well-known classes of antimicrobial agents to which many clinically relevant pathogens are now resistant [1]. Antibiotic resistance occurs when bacteria change in some way that reduces or eliminates the effectiveness of drugs, chemicals, or other agents designed to cure or prevent infections. The bacteria survive and continue to multiply causing more harm. Bacteria can do this through several mechanisms. Some bacteria develop the ability to neutralize the antibiotic before it can do harm, others can rapidly pump the antibiotic out, and still others can change the antibiotic attack site so it cannot affect the function of the bacteria. Therefore, provision of antimicrobial agent that can tackle this resistance problem remain the priority of synthetic chemist [2]. Resistance microbes are increasingly difficult to treat, requiring alternative medication or higher dose. Hence, calls for new antibiotic therapies have been used, but new drug-development is becoming rarer [3]. Cephalosporin are bactericidal and have the same mode of action as other β -lactam antibiotics (such as penicillin), but are less susceptible to β -lactamases. Cephalosporin disrupt the synthesis of the peptidoglycan layer forming the bacterial cell wall. The peptidoglycan layer is important for cell wall structural integrity. The final transpeptidation step in the synthesis of the peptidoglycan is facilitated by transpeptidases known as penicillin-binding proteins (PBPs) [4]. Resistance to cephalosporin antibiotics can involve either reduced affinity of existing PBP components or the acquisition of a supplementary β -lactam-insensitive PBP. Currently, some *Citrobacter freundii*, *Enterobacter cloacae*, *Neisseria gonorrhoea*, and *Escherichia coli* strains are resistant to cephalosporin. Some *Morganella morganii*, *Proteus vulgaris*, *Providencia rettgeri*, *Pseudomonas aeruginosa* and *Serratia marcescens* strains have also developed resistance to cephalosporin to varying degrees [5]. Silver and its compounds have long been used as antimicrobial agents in medicine. Silver sulfadiazine is a widely used broad-spectrum antibiotic ointment, effective against a broad range of bacteria and some yeast [1]. Copper and its alloys are natural antimicrobial material. Ancient civilizations exploited the antimicrobial properties of copper long before the concept of microbe became understood in the nineteenth century [6]. Mechanochemistry refers to reactions, normally of solids, induced by the input of mechanical energy, such as by grinding in ball mills. It is becoming more intensely studied partly because it can promote reactions between solids quickly and quantitatively, with either no added solvent or only nominal amounts. Historically, it has been a sideline approach to chemical synthesis, and solution-based methods have been adopted by default [7]. In continuation of our work on antibiotic resistance [8], this paper reports the effect of mechanochemically synthesized copper (II) and silver (I) complexes with cefuroxime on some cephalosporin resistant bacteria.

2. Materials and Methods

All the chemicals used were of analytical grade. These were obtained from Bristol Scientific Company Limited, and used without further purification. The ligand used is cefuroxime (Cfu), while the metals used are copper chloride dihydrate $[\text{CuCl}_2 \cdot 2\text{H}_2\text{O}]$ and silver nitrate $[\text{AgNO}_3]$. IR spectra of the complexes in KBr pellets were obtained in the range of $4000\text{--}400\text{ cm}^{-1}$ using FTIR spectrometer. Metal analysis was determined by atomic absorption spectroscopy using Perkin-Elmer Spectrometer, model 3110. UV-Vis spectra were obtained on UV-2550 Shimadzu Spectrophotometer in the wavelength range of $200\text{--}800\text{ nm}$.

Synthesis of the Complexes

Literature procedure [9] was modified and used for the synthesis of all the metal complexes by mechanochemical method. Cefuroxime (10 mmol, 4.25 g) and copper chloride dihydrate (10 mmol, 1.705 g) were weighed carefully and transferred into a mortar. The two reactants were then crushed (ground) for twenty (20) minutes to obtain homogenous powder. The powder was removed from the mortar and stored in a desiccator. Same procedure was used for silver nitrate (10 mmol, 1.699 g) and cefuroxime (10 mmol, 4.25 g).

Equation for reaction

Where CFU = Cefuroxime

Antimicrobial Screening

The *in-vitro* antimicrobial activities of the antibiotics and their metal complexes were assayed using disc diffusion method against the following microorganisms; *Streptococcus pneumoniae*, *Bacillus subtilis*, *Salmonella typhi*, *Klebsiella pneumoniae*, *Escherichia coli*, Methicillin- resistance *Staphylococcus aureus* (MRSA), *Pseudomonas aeruginosa* and *Staphylococcus aureus*. The suspension of each micro-organism was added to a sterile nutrient agar medium, then spread on the sterile Petri dish plates and allowed to set. Different concentrations (30, 20 and 10) mg/mL of antibiotics and their metal complexes in methanol were placed on the culture media and incubated for 24 hrs at 37°C. Activities were determined by measuring the diameter of the zone of inhibition (mm). The antibiotics and their complexes that showed zone of inhibition of 10 mm and above were further assayed for minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) using samples concentration of (6, 4 and 2) mg/mL in methanol using same bacterial species in peptone water [10].

3. Results and Discussions

The complexes of copper and silver ions obtained are air stable light green and white powders respectively. Both complexes are soluble in polar solvents such as distilled water, methanol, ethanol and dimethylsulfoxide (DMSO). The solubility of the complexes in polar solvents, suggest that the compounds are probably polar. Similar observation was made by [11]. The melting point of the complexes of copper and silver are 110 and 120°C respectively (Table 1). The variation in the melting point of ligand and that of the complexes suggest formation of new compound and also evidence of complexation [12]. The molar conductivity of the complexes falls between 3.6 and 4.5 Scm^2/mol (Table 1). This suggests the complexes are non-electrolytes [13].

Infrared spectra

The infrared spectra data of the complexes and its ligand are presented in Table 2. The band assignments are based on comparison with similar studies on mixed ligand complexes and some drug based metal complexes [11]. The vibrations centered around 3190 cm^{-1} in the free ligand was assigned to $\nu(\text{O-H})$ stretching frequency, which upon complexation undergo shift in the complexes. The band at 3560 cm^{-1} in the free ligand was also assigned to $\nu(\text{N-H}_2)$ vibration of amine group. While, the band at 1550 cm^{-1} was assigned to $\nu(\text{C=N})$ vibration. Similar observation was made by some workers [14].

The strong intensity band attributed to $\nu(\text{C=O})$ vibration stretching was observed in the spectra of the free ligand at 1720 cm^{-1} . The relevant bands were observed in the metal complexes with lower wavelength shift as compared to the ligand couple reduction in their intensities (Table 2). The appearance of new bands at 620 and 630 cm^{-1} in the spectra of the complexes which is assignable to $\nu(\text{M-O})$ stretching, suggest formation of the complexes.

Electronic spectra

The electronic spectral data of the cefuroxime and its complexes are presented in Table 3. Based on previous assignments of related complexes [15-17]. The transition around 349 nm in the spectra of cefuroxime (CFU) was assigned to $\pi \rightarrow \pi^*$ transition (Table 3). Similar observation was made in previous literature [17]. $[\text{Cu}(\text{CFU})_2\text{H}_2\text{O}]$ complex showed low intensity band at 340 nm assigned to MLCT. The $[\text{Ag}(\text{CFU})\text{NO}_3]$ complex, showed absorption band at (287, 301 and 313) nm which indicate a bathochromic shift relative to the free ligand and a weak interaction between the ligand and silver ion which can be assigned to MLCT [16].

Microanalysis

The microanalysis of the metal complexes is presented in Table 4. The results revealed that the % C, H and N are in good agreement with the proposed structures. From the data obtained, it appears that the complexes analyzed as $[\text{Cu}(\text{L})_2\text{H}_2\text{O}]$ and $[\text{Ag}(\text{L})\text{NO}_3]$. Where L = CFU.

Antimicrobial studies

Transition metal complexes play a vital role in biological study, some of these have now been widely studied for their antimicrobial and anticancer properties [15] and extensive investigation in the field of metal complexes have been reported [18]. A novel Cu (I) and Ag (I) complexes has also been studied with their antimicrobial activities [16]. In continuation of this discovery, the present study synthesized a new Cu (II) and Ag (I) complexes with cefuroxime using mechanochemical method, and the antimicrobial effects were observed to see whether the compounds involved in this study exhibit any activity or not. In the present study, both ligand and complexes have been evaluated against both gram positive and negative bacteria such as: *Streptococcus pneumoniae*, *Bacillus subtilis*, *Salmonella typhi*, *Klebsiella pneumoniae*, *Escherichia coli*, MRSA, *Pseudomonas aeruginosa* and *Staphylococcus aureus*.

The results of the inhibition zones of the selected bacteria due to effect of the ligand and its complexes are presented in Table 5. The results obtained revealed that the complexes were more effective against the microorganism than the ligand. The data also showed that *Bacillus subtilis* was inhibited to the greatest degree by the prepared complexes followed by *Staphylococcus aureus*. While, *Escherichia coli* and *Pseudomonas aeruginosa* were not inhibited by both the ligand and the complexes at all concentration (Table 5). The complexes also inhibit *Klebsiella pneumoniae* at concentration of 20 and 30 mg/mL when compared with the ligand which shows less activity at same concentration. **Structure of the complexes**

The analytical data of this study revealed that coordination of cefuroxime to the metal ions occurs through oxygen atom of the carboxylate anion, oxygen atom of water molecule and oxygen atom of carbonyl for both complexes to give a coordination number of five. (Fig 1 and 2). This is similar to our previous report [8]

From the result of minimum inhibitory concentration (MIC), it appears that both the ligand and the complexes have MIC of 6 and 8 mg/mL on MRSA, *s. aureus*, *B. subtilis* and *S. typhi*. However, [Ag(CFU)NO₃] has MIC of 4mg/mL on *S. pneumoniae* and 6 mg/mL on both *E.coli* and *P.aeruginosa* (Table 6).

The MBC result also shows that both the ligand and the complexes have MBC ranging from 6-10 mg/mL on microorganism tested (Table 7).

4. Conclusion

Based on the results obtained from the analysis of both compounds, five coordinated complexes were proposed. Measurements of inhibition zones of the ligand and complexes showed that the prepared complexes have enhanced antibacterial activity on the cephalosporinresistance bacteria than the ligand.
