ABSTRACT- A Radio controlled airplane is a small flying machine that is controlled by motorist using a handheld transmitter. The RC plane is controlled by motorist on ground using a transmitter communicating with a receiver transferring signals to servos on board the plane. This RC plane has all the dynamics characteristics which are present in actual aircrafts. The aircraft considered in this study was designed to have optimum lift and drag characteristics. This was achieved by choosing the optimum values of fuselage length, wingspan, elevator, rudder confines and the all up weight determined by a series of iterative analysis. In addition, the optimum angle of attack analogous that a cell condition does not do was also determined. The modelling was done using marketable software CATIA V5R18. The lifting line proposition system was used in XFLR-5. This analysis for determining the parameters of the RC plane was done using XFLR- 5. This was also indicated by the system of computational fluid dynamics using marketable software ANSYS 15.

Keywords - RC plane, Fuselage, Wingspan, Elevator, Rudder, Drag, Lift, All up weight, stall, and angle of attack.

I. INTRODUCTION

The main aim of this project was to design, analyze and build an RC plane. This involves understanding the various aerodynamic forces and moments acting on the plane, choosing the right motors, controllers for its operations and hence making it fly. Hence this project involved optimization of various parameters for an enhanced flight. In order to achieve the

stated objective, extensive literature review was done in determining the various parameters for building of the plane. Authors in [1] suggest development of a Canard type aircraft, with the mission of aerial reconnaissance and surveillance. Ryan et al [2] provide insight into flapping flight configuration that provided an insight into improved aerodynamic performance, improved maneuverability, and hover capabilities. Luca et al [3] provide a review of state of art with respect micro and nano aerial vehicles, which helped better understanding of different design and engineering principles for such vehicles. Reference [4] provided detailed information on RC controlled aircrafts design and build. Based on all the literature review and available knowledge, it was decided to systematically design, analyze and build an RC plane. In addition it was decided to develop such a plane, to maximize the aspect ratio, minimize the wing loading and optimize the weight. Basic terms like lift coefficient, tip, root chord, taper ratio etc... help understand the aerodynamics characteristics of flight while the actual movement of air over the airfoil help understand the behavior of flight in air. Keeping these considerations in mind the design and optimization were done.

The aim of this paper is therefore to explain the systematic methodology followed for designing, analyzing and building the RC plane including details of optimization. The following are the major steps in this process:-

- Selecting various design targets
- Selecting the type of geometry
- Optimization of parameters to obtain the best performance
- Determining the stress points, critical points on the wing and fuselage (for

III.DETAILS OF DESIGN

Initially the parameters were chosen using the basic formulae of aspect ratio, taper ratio and then analyzed and validated using ANSYS15. The aspect ratio was chosen to be in the range of 6-6.5, the wing loading .46 - .55g/cm², surface area of the wing 1250 - 1350cm² and weight of the wing to be 500g. The all up weight, lift and drag forces, lift and drag coefficients etc.. were optimized on the basis of these design parameters. The aim was to maximize lift. The free stream velocity of operation was chosen to be 1500cm/s. Based on this the stall speed was also determined. Since it was chosen to make it an aerobatic plane a symmetric airfoil had to be chosen. Also in the region of the ailerons and wingtip a symmetric airfoil would help increase the range of angles of attack to avoid spin and stall. Thus, relatively a large range of angles can be used without boundary layer separation. Hence NACA0016 wing configuration was considered. Here, the number16 indicates that the airfoil has a 16% thickness to chord length ratio. With this, the wing length was fixed at 90cm having a fixed chord length of 15cm.

Figure 3 shows the particular airfoil considered for the purpose of this study.

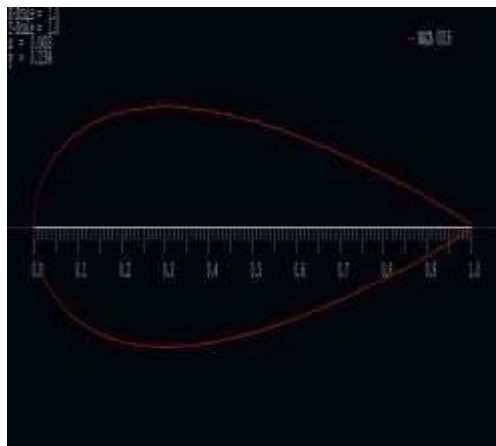

Fig 3 NACA0016 Airfoil

Further, an analysis of the airfoil was done and the neutral point (i.e. where the coefficient of moment is 0) was found to be at 3.47 cm from the tip of the airfoil. Neutral point is basically the point where coefficient of moment is 0 and it coincides with the center of lift for a symmetric airfoil. Also, the center of gravity must lie ahead of the neutral point for positive stability. This was since stability was required as explained earlier under stability.

The neutral point was found using XFLR-5 and validated using ANSYS15

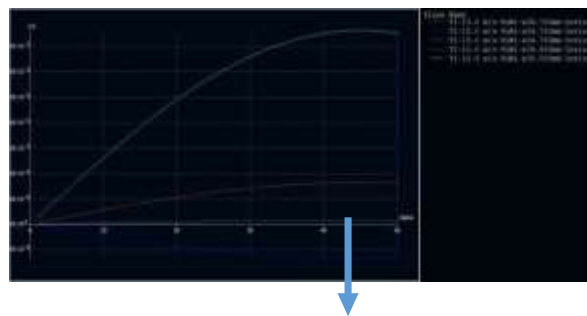

Fig 4: Graph of the coefficient of moment v/s alpha tending to a straight line

Figure 4 shows the variation of the coefficient of moment v/s alpha. The neutral point was found to be 3.47cm.

Figure 5 shows the validated data from an ANSYS run confirming the location of the neutral point at 3.47cm. Since, analysis is a more accurate software and values are obtained by the use of k-w turbulence module and good meshing procedures this value is used for all further calculations. Also the neutral point is found to lie between 3.47 and 3.48 since the moment changes its value from the current to+.00328. Hence ,3.47 is taken as the approximate value

Moments -Moment Center (1 3.47 0) Moment Axis (1 3.47 0)			
Moments			
Zone	Pressure	Viscous	Total
Airfoil region	-0.028518209	-0.012876024	-0.041394233

Fig 5 Data from ANSYS run

The pressure forces acting on the airfoil were also analyzed in order to place the wing in such a way that maximum lift were to be obtained. Figures 6 and 7 below show the pressure contours on the wing

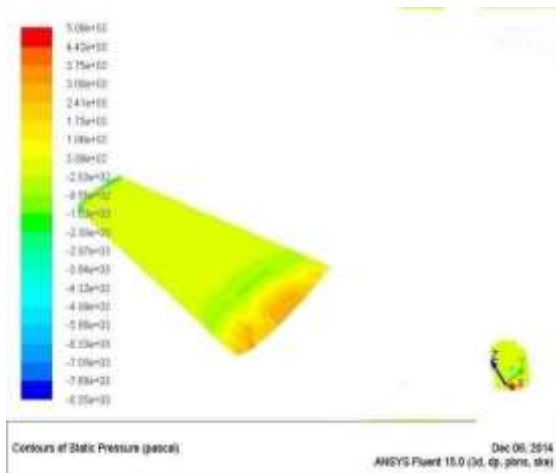

Fig 6 Pressure contour on the wing

The static center of gravity margin (c.g. margin) or static margin is the distance between the center of gravity and the neutral point. It is usually quoted as a

Fig 7 Pressure contour on the wing

percentage of the Mean Aerodynamic Chord. The center of gravity must lie ahead of the neutral point for positive stability/ If the center of gravity is behind the neutral point, the aircraft is longitudinally unstable .This concept is used to find the neutral point and also the tail sizing. From front till 40 cm along the length of the fuselage, the cross section is rectangular and then it converges to a trapezoidal cross section.

The other parameters were chosen after a more detailed analysis of wing which involved batch analysis and determination of lift and drag forces which were all done with the help of ANSYS and XFLR-5 [5]. Figure 8 shows the static pressure distribution on the wing surface.

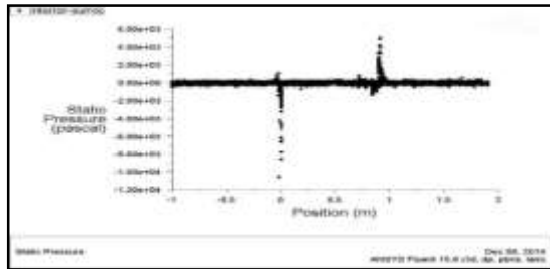

Fig 8 Static pressure on the wing surface

Figures 9 and 10, show the distribution of pressure and velocity of airflow on the wing surface. The velocity on the lower surface is lower than the velocity of air on the upper surface. This confirms that the pressure of air on the lower surface of the wing is higher and on upper surface is lower. Thus by Bernoulli's theorem this would help lift the aircraft. Based on all the above analysis, the wing was then designed for a lift coefficient of 1.15 and a wing of NACA0016 airfoil configuration having a wing span of 90cm and chord length of 15cm was considered. Then the same values were confirmed once again by a batch analysis. The symmetric airfoil provided good maneuverability and not a very high lift (provided good lift upto stall condition and no stall occurred. The overall lift wasn't very high)

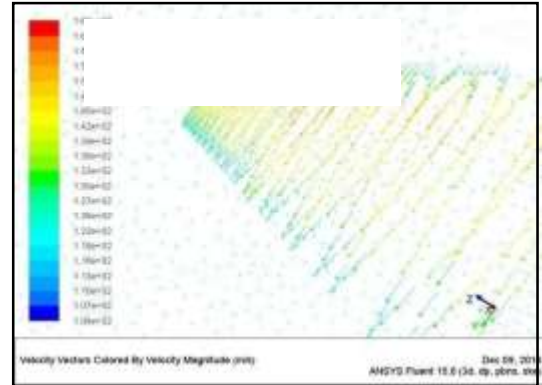

Fig 9 Wing analysis and airflow over the wing

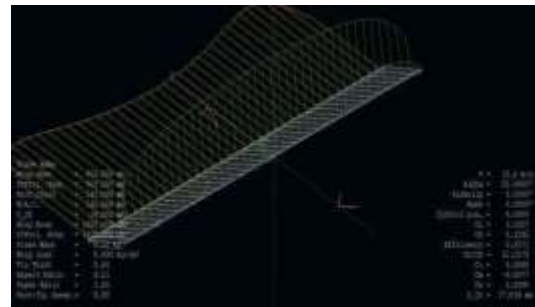

Fig 10 Wing analysis (CL and CD)

Figure 10 shows the wing analysis which helped to determine the lift coefficient (CL) and drag coefficients(CD) using XLFR-5. From this the lift and drag forces are estimated using equations 2 and 3 below.

$$F_L = \frac{1}{2} \rho v^2 C_L$$

$$F_D = \frac{1}{2} \rho v^2 C_D$$

Where, F_L – Lift force F_D – Drag force
 ρ – Density v - velocity
 C_L - lift coefficient C_D – drag coefficient

Thus the lift and drag forces were found to be 129.375kN and 12.79kN respectively by using the above formulae. These were then validated in

ANSYS software.

Figure 11 shows the data generated from ANSYS validating the values of lift and drag forces. (1 0 0) and (0 1 0) represent the direction of drag and lift forces. The data obtained for the lift and drag forces from ANSYS, 137.9kN and -11.364kN (negative sign due to opposite direction of force) validate the results from the formulae. Since XFLR-5 produces approximate values and ANSYS (Fluent) produces more accurate values due to the use of better models such as k-e turbulence model etc, the values

Where, F_L – Lift force F_D – Drag force
 ρ – Density v - velocity
 C_L - lift coefficient C_D – drag coefficient

obtained from ANSYS were considered for further calculations.

Based on all the above analysis, the wing was then designed for a lift coefficient of 1.15 and a wing of NACA0016 airfoil configuration having a wing span of 90cm and chord length of 15cm was considered. Then the same values were confirmed once again by a batch analysis. Taking all these parameters into consideration the wing design was completed.

A. FUSELAGE

Next the fuselage design and related parameters were to be determined. Extensive literature review and analyzing of various designs were done. The elevator and rudder

Thus the lift and drag forces were found to be 129.375kN and 12.79kN respectively by using the above formulae. These were then validated in ANSYS software.

Figure 11 shows the data generated from ANSYS validating the values of lift and drag forces. (1 0 0) and (0 1 0) represent the direction of drag and lift forces. The data obtained for the lift and drag forces from ANSYS, 137.9kN and -11.364kN (negative sign due to opposite direction of force) validate the results from the formulae. Since XFLR-5 produces approximate values and ANSYS (Fluent) produces more accurate values due to the use of better models such as k-e turbulence model etc, the values obtained from ANSYS were considered for further calculations.

dimensions were determined subsequently and the plane was modeled with the exact values in CATIA to determine the center of gravity i.e. at which the entire mass is assumed to be concentrated.

Forces - Direction Vector (1 0 0)			
Zon	Pressure		Total
Airfoil-	-6.354	-5.009	
Net	-6.354	-5.009	-

Forces - Direction Vector (0 1 0)			
Forces (kN)			
Zone	Pressure	Viscous	Total
AirfoilRegion	137.932	0.001	137.934

Fig 11 ANSYS Output of Forces

- Horizontal Stab: 20% - 25% of the wing area
- Elevator: 20% - 25% of the horizontal stab chord
- Vertical Stab: 7% -12% of the wing area
- Rudder: 30% - 50% of the verticalstab chord
- Fuse Length: 70% of wing span (measured from nose/thrust washer to rudder hinge line).

From this analysis the following dimensions were obtained. The length of the fuselage was optimized to be 65cm. The breadth of the fuselage was 7cm. From front till 40 cm along the length of the fuselage, the cross section is rectangular and then it converges to a trapezoidal cross section. The wing was mounted at 21cm from the tip of the motor mount. The battery was placed at the center of gravity which was required for stability and balancing of forces of the plane. At the aft part of the fuselage the elevator and rudder were attached, dimensions of which were as follows.

B. ELEVATOR

The total length of the elevator was 25cm and width 4.5. The V shaped portions were found to be 14cm on both side and the last side of the trapezium to be 9.3cm. It was mounted in such a way that its center coincided with fuselage center line.

C. TAIL SIZING

For tail sizing the concept of longitudinal stability was used. From this the dimensions were obtained. The moving part of the rudder was found to be 12cm in length and 4cm in width. 0.5cm was cut in order to allow its movement by the servo mechanism. The hinged part was of length 15cm and width varying from 7 cm at the bottom to 2 cm at the top. The attaching part was joined at a distance of 3cm from the

base.

D. AILERONS

The ailerons were 6cm in width and 23cm in length. They were attached to the wing as per conventions in figure 1 that is at a distance of 8cm from the tip of the wing.

E. MOTOR MOUNT AND LANDING GEAR

The motor mount dimensions were 11 cm x 7cm that is same as the fuselage and 1cm on each side was bent in a near perpendicular manner so as to act as a mount on the fuselage. The landing gear was 11cm wide and 25cm long with the bent part bent at an angle of 120° . The rear landing gear was made of 2 perpendicular strips of length 4cm and width 7cm. Figure 12 below shows the complete plane model in CATIA with the above parameters. This was then analyzed to obtain the coordinates of center of gravity of the resulting plane configuration.

After determining the various forces acting on the plane, the plane was modeled to full scale parameters and then the prototype was built.

Figure 13 shows the full scale CATIA model of the resulting aircraft.

Fig 13 CATIA model of the plane

Fig 14 Centre of mass coordinates

Figure 14 shows center of mass coordinates as generated by CATIA

Thus, the position of center of gravity was found to be at 20.782 cm (That is right below the wing) and the total mass of the plane to be 870g.

Thus the final parameters of the plane were as follows :-

- Length of half wing = 45.0cm
- Wing span = 90.0cm
- Breadth = 14.5cm
- Aspect ratio = 6.21
- Total weight = 870g
- Weight of wing = 500g
- Surface area of wing = 1305cm²
- Neutral point (with respect to leading edge) = 3.14
- Stall angle = 12⁰
- Velocity of plane = 1500cm/s

Component	Area [m ²]	Volume [m ³]	Mass [kg]	Gx [cm]	Gy [cm]	Gz [cm]
Fuselage	0.360	0.003	0.06	12.229	2.60933	-44.498
Motor mount	0.024	6.39363e-005	0.064	18.343	-46.188	-40.631
Landing gear	0.025	6.08716e-006	0.006	-109.908	93.036	-49.155
Elevator	0.066	0.000122566	0.123	53.653	6.24184	-36.649
Rudder	0.028	4.93731e-005	0.049	106.768	5.9531	-30.077
Wing	0.130	0.000548569	0.549	49.020	18.8569	-32.087
Propeller	0.009	1.6498e-005	0.016	22.243	-56.564	-43.627
Wheel axle	0.004	3.18086e-006	0.003	-229.629	89.668	-60.125
Plane	0.662	0.003	.87=870g	20.782	25.9370	-41.940

- Stall speed = 880cm/s
- Airfoil used is NACA 0016
- Coefficient of lift=1.15
- Length of fuselage 65.0cm
- Drag force =12.79kN
- Leading edge of wing =21cm from motor tip
- Reynolds number range =100000 to 150000
- Mean aerodynamic chord (A_c) =25% of chord behind leading edge.

III. MANUFACTURING OF THE PLANE

After finalizing upon the parameters the process of building the prototype was started. These were the procedures adapted in building of various parts of the model

A. WING

Since the lift force was 137kN, a material which could withstand that force and was light weight had to be chosen. Hence high density thermocol (of density 0.03g/cm³) was considered a good option. Initially the wing was cut to 90cm using the technique of hot wire cutting and then sanded using high and low grade sandpaper to perfection to obtain the final shape. A spar made of metal was inserted (as shown in the final model at the end) in order to withstand impact forces.

B. FUSELAGE

The fuselage was primarily made of Corox a material like plastic. It was 4mm in thickness. The bonding was achieved using high strength glue. In order to provide additional stiffness or strength at stress points thin strips of galvanized metal sheets about 1mm in thickness were cut and placed at stress points. These were the points where the landing gear was connected and the point that would be held during launch. A section (horizontal) was cut out to fix the wing in place.

C. ELEVATORS RUDDER AND AILERONS

The elevators, rudder and ailerons were

made of the same 4mm thick Corox, since it had high toughness and could be rigid throughout the flight

D. LANDING GEAR AND MOTOR MOUNT

The front and rear landing gear were made of aluminum strips since they were proven to be light weight and sturdy to withstand the impact forces during landing. They were first bent at 120° to a length of 25cm as specified earlier. A motor mount was made of sheet metal (galvanized) and holes were driven to screw in the landing gear as well as motor mount onto the fuselage using nuts and bolts. It was bolted so as to prevent its movement and withstand the thrust produced by the motor basically to ensure that it did not detach from the fuselage at any point in time.

IV. ELECTRONICS USED ONBOARD THE PLANE

A. MOTOR

The motor used was 110g in weight and worked on an 11V battery. A motor mount was made of sheet metal (galvanized) and holes were driven to fasten the motor onto it. It was bolted so as to prevent its movement and withstand the thrust produced by the motor. The battery

was in turn connected to the ESC which was connected further to servos. The propeller was 11"/7" in dimension (made of carbon fiber) and was mounted onto the motor using a domed nut provided. The thrust required were calculated and the motor was chosen accordingly. Some of the specifications were as follows :-

Rotational Speed:
1050(kV) RPM/V Motor
Weight (Motor only):
110g Motor shaft
Diameter: .4cm

B. ELECTRONIC SPEED CONTROLLERS (ESC)

The ESC's are used to control the speed or thrust produced by the motor. It has 3 ends 2 of which are connected via Deans" plug to the battery and the other end to the receiver. The other 3 ends of the ESC are connected to the motor by soldering it using connectors of 2mm. This was then run to maximum throttle and the effect was noted.

C. BATTERIES

The battery used has a rated voltage of 11V and 2200 mah. current. This was chosen depending on the time the plane could be airborne given the thrust produced by the motor which was the major current drawing factor apart from servos. It was found that the flight could last for 4-5 minutes with the use of 2200mah Lithium polymer batteries and was hence chosen.

D. TRANSMITTER AND RECIEVER

To control the movement of elevators for takeoff and landing and also the throttle of the motor a 2.4 GHz transmitter and 6 channel receiver was used. In particular, 1channel was used for the ailerons, 1 for the rudder, 1 for the elevators and other for the motor. Two other

channels were left free.

v. CONCLUSIONS

An attempt has been made to systematically design, analyze, build and fly a prototype RC plane. This project provided the team an insight into basics of aircraft design, engineering, building and testing albeit on a small scale. The team also could learn aircraft technology fundamentals and use design and analysis tools. The project also provided an opportunity for multi-disciplinary team to work together and understand the interactions. The teams also have been able to document the lessons learnt to be further used in the upcoming aerospace projects by the same team.
